

Final Project Use Case(s): Podcast Transcript Parser

Inspired by Phil Goddard's final project, [here](#).

Proposed use case(s) for the app:

Input

As a user I can use a web form to:

- Input base podcast information (Objective A):
 - Podcast Name
 - Filename for storage (Objective B)
 - Title (optional)
 - Raw transcript JSON
- Select one of two storage options:
 - **Store Only**
 - **Clean**, which will:
 - Organize all speakers in the transcript, including:
 - Calculate each speaker's proportional talk time
 - Separate the host and guest(s) from the ad reads using talk time
 - Label each primary speaker
 - Group speakers' dialogue into turns
 - Organize individual words into consecutive strings, then convert them into dialogue objects
 - Rebuild the transcript with cleaned text
- Click a button to submit the form

Output

The system returns one of two outputs (Objective C), depending on the user's request:

- **Store Only**
 - A confirmation message that the raw, original transcript file has been saved (Objective D)
 - The transcript ID
- **Clean**
 - A cleaned version of the transcript, organized by speaker turns
 - The filename and cleaned transcript ID (Objective D)
 - A list of excluded speaker turns that have been flagged as ad reads

Objectives

- A. Have a front-end that is implemented as a simple HTML form
- B. Have a web-accessible API that lets your form access your application
- C. Have a services layer that coordinates the business logic of your application
- D. Use a MySQL database, either writing data to the database, or reading data from the database
